Abstract

Introduction: In this study, the effects of the ethanolic extract of aerial parts (stem and leaves) of *Smyrniium cordifolium* (*S. cordifolium*) Boiss on the ethylene glycol(EG)-induced kidney calculi in rats was investigated.

Materials and methods: Thirty-six male Wistar albino rats were randomly divided in 6 groups. Group I (normal control), Groups II (control of EG) to VI received EG 1% v/v in water for 28 days. Animals in Groups III and IV (preventive groups) received ethanolic extract of stem and leaves of *S. cordifolium* in 200 mg/kg and 400 mg/kg orally in water for 28 days, respectively. Groups V and VI (treatment groups) received extract in 200 mg/kg and 400 mg/kg orally in water from 15th to 28th day, respectively.

Results: Results showed that the level of urine oxalate, blood urea and creatinine in EG group vs. normal control significantly increased ($P<0.001$). Extract did not show significant effect on urinary oxalate, urine volume and other blood biochemical parameters in the treatment groups (V and VI). Provision of extract resulted in significantly lower levels of urine oxalate and higher level of volume, serum creatinine and blood urea in III and IV groups as compared with Group II ($P<0.05$).

Conclusion: These observations enable us to conclude that the ethanolic extract of aerial parts of *S. cordifolium* Boiss is effective against EG induced urinary calculi in rats.

Keywords: Kidney stone, Ethyl glycol-induced kidney calculi, *Smyrniium cordifolium* Boiss

Introduction

Urinary calculi are the third prevalent disorder in the urinary system, which may cause obstruction, hydronephrosis, infection, and hemorrhage in the urinary tract system (1). The risk of developing urinary calculi in adults appears to be higher in the western hemisphere (5–9% in Europe, 12% in Canada, and 13–15% in the USA) than in the eastern hemisphere (1–5%) (2). However, approximately 75%

of stones are primarily calcium oxalate (3). Extracorporeal shock wave lithotripsy, percutaneous lithotomy, transureteral lithotripsy, and even laparoscopy are widely used to remove the calculi. However, using these invasive procedures is not cost effective and may also lead to severe complications. Thus, more efforts are needed to better assess medical therapy and to develop new agents that can be used

either alone or combined to prevent stone formation more efficiently with fewer side-effects. Therefore, it is worthwhile to replace these conventional treatments with medicinal plants or phytotherapy. Medical plants are used worldwide and there is an increasing interest in research in this area to provide a scientific basis for their beneficial effects (4-9).

Ethylene glycol (EG) has two toxic metabolites; glycolic acid, which is responsible for the acidosis, and oxalic acid (10). The toxic effects increase free radical production and lipid peroxidation.

Smyrniium cordifolium is one of the range plants in native pasture in mid-south of Iran especially in Kohgiluyeh and Bovir Ahmad province (southwest of Iran). Genus *Smyrniium* belongs to *Umbelliferae* family and is used by people as an herbal medicine in treatments for internal organ edema, especially in bladder and kidney problems. The roots, stems and leaves contain strongly odored phenolic essence. Stem and leaves of *S. cordifolium* are used traditionally for treatment of kidney stones in Iran (11). In another study reported that essential oils obtained from stem leaves, roots and fruit of *S. cordifolium* have antibacterial effects, which they claim are due to the large amounts of sesquiterpene hydrocarbons such as curzerene, curzerenone and germacrone (12). *S. cordifolium* is a native of Iran and eaten as a green by some people in west part of Iran. It is often used internally for bladder and kidney swelling (11).

Though, it is used as a folk medicine for treatment of renal calculi, its effectiveness and mechanism as anti-urolithiatic agent is still unknown. We have described in this study preventive and treatment effects of renal calculi.

Materials and methods

Thirty-six male Wistar albino rat (250-350 g) were randomly divided into six equal groups. Group I received water and served as normal control. Group II to VI received EG 1% v/v in water for 28 days. Group II

served as EG control group. Animals in Group III and IV (preventive groups) received ethanolic extract of stem and leave of *S. cordifolium* in 200 mg/kg and 400 mg/kg orally in water for 28 days, respectively. Group V and VI (treatment groups) did not receive extract for first 14 days. These groups received extract in 200 mg/kg and 400 mg/kg orally in water from 15th to 28th day, respectively (13).

Twenty-four hr. urine specimens were collected on day 0 and 28 of the study by keeping each rat in separate metabolic cage. Urine volume was measured and kept under refrigeration (2-8 °C). Urinary oxalate was measured by oxalate kit by spectrophotometer. Blood samples were collected from heart on day 28 and serological parameters for renal functions were measured.

The animals were sacrificed soon after blood collection under the continued effect of anesthesia. Both kidneys were removed and were fixed in 10% neutral buffered formalin for at least 48 hours. Then, tissue samples were embedded in the paraffin block. Sections in 5µm thickness were stained with hematoxylin-eosin and evaluated under optical light microscope.

Statistical analysis

One-way ANOVA and post-hoc Tukey tests were used for analysis of serum and urine parameters. The non-parametric Kruskal-Wallis test and Mann-Whitney *U* test were used for comparison of CaOx deposits. P values of less than 0.05 were considered statistically significant. Data were expressed as mean ± standard error (SEM).

Results

Urinary parameters: There was no statistically significant difference in urinary volume and oxalate in all the groups on day 0. Urinary oxalate was significantly increased after EG administration. Urine volume was significantly decreased by EG in group II

($P < 0.05$). Urine volume in the preventive groups was increased but not significant and in treatment groups was significantly increased (Table 1, $P < 0.05$). A significant decrease in the urinary excretion of oxalate was observed in both the preventive groups (III and IV; $P < 0.01$), but in the treatment groups (V and VI), not significant change was present in compared to the EG group (Table 2).

Biochemical parameters: EG administration increased the values of blood urea and serum creatinine significantly as compared to the normal control group. *S. cordifolium* extract showed the significant improvement in the renal parameters in the preventive groups ($P < 0.05$). Renal parameters were non-significantly improved in the treatment groups (Table 3).

Histopathological evaluation: The normal control group and only received extracts groups had kidney with normal histology (Figure 1). EG treated rats, the epithelium of renal tubules revealed vacuolar degeneration and necrosis and glomeruli had become atrophy. Hyaline casts were observed in the most tubular lumen (Figure 2). In the preventive groups that received 200 and 400 mg/kg of *S. cordifolium* extract for 28 days, renal lesions including degenerative changes and necrosis of the epithelial tubules reduced, and less hyaline casts were present in their lumens (Figure 3). No remarkable difference was observed between two treated groups. Also, induced injuries by EG decreased in treated groups with 200 and 400 mg/kg of *S. cordifolium* extract (Figure 4). No remarkable difference was observed between concentrations.

Discussion

Our data demonstrated that aqueous extract of stem and leaves of *S. cordifolium* had a preventive effect on kidney calculi formation in the kidney of rats. The aqueous extract also decreased the number of CaOx calculi in the treated group and therefore, demonstrates a therapeutic effect, albeit trivial, on the disruption of CaOx calculi formed in the kidney due to EG consumption. The *S. cordifolium* extract with the dose of 400 mg/kg had a significant preventive effect on the formation of CaOx kidney calculus. To our knowledge, this is the first report on the effect of aqueous extract of the *S. cordifolium* on the prevention and treatment of CaOx calculi.

Calcium oxalate crystals in the nephrons cause damages of the epithelial cells, and consequently produce free radicals and some components inducing heterogenous crystal nucleation that result in aggregation of crystals (14). It has been reported that CaOx calculi similar to the struvite calculi may have a bacterial origin (15). Khan ahmadi et al (2015) studied the antioxidant and antibacterial activities of soluble compounds in extracts from the aerial parts of fresh *S. cordifolium* Boiss. They reported that the extracts of this plant

contain antioxidant and antibacterial activities (16).

In urinary calculi, the glomerular filtration rate (GFR) decreases, due to the obstruction of the urine outflow by urinary stones. Therefore, the waste products particularly nitrogenous substances such as urea, creatinine and BUN accumulate in blood. EG increases blood urea and creatinine levels significantly due to impairment in renal function. EG has two toxic metabolites; glycolic acid, which is responsible for the acidosis, and oxalic acid, which precipitates as calcium oxalate monohydrate (COM) in the kidney, and causes proximal tubular cell necrosis. The toxic effects increase free radical production and lipid peroxidation (17). EG is metabolized into glycolaldehyde acid, glycolic acid, glyoxylic acid, and oxalic acid. The formed oxalic acid is largely excreted in urine as oxalate. It is precipitated by calcium ions to form CaOx crystals (18).

In the present study, *S. cordifolium* extract had significantly decreased degenerative changes and necrosis of the proximal tubules, and also levels of creatinine and urea in the different experimental groups.

Diuretic action is also needed to increase the amount of fluid going through the kidneys and flush out the deposits. Increasing urine volume reduces the saturation of the salts and prevents the precipitation of the crystals at physiological pH (19). *S. cordifolium* Boiss is a spring plant which was traditionally used as diuretic plant and expellant for kidney stones (20).

In the present study, the histopathological findings supported the data obtained from biochemical and urine analysis. However, EG treated group which showed swelling and vacuolar degeneration of the tubular epithelium as well as hyaline cast in the tubular lumen that indicate excretion of protein through the glomeruli but those from treated rats were apparently of near normal architecture with very few crystals and deposits. The effect was more pronounced in higher dose group.

Calcium oxalate crystals and high levels of oxalate in the nephrons can damage the epithelial cells, and consequently, the cells may produce some products as well as free radicals, inducing heterogeneous crystal nucleation and cause aggregation of crystals (13).

The exact mechanisms through which *S. cordifolium* extract affects CaOx calculi are still under debate. It is speculated that *S. cordifolium* extract could prevent the formation of CaOx calculi and their disaggregation through its anti-inflammatory and antioxidant mechanisms. Furthermore, extract may interfere with the process of epithelial cell damage induced by crystals. Several studies have reported

that flavonoids have anti-inflammatory and antioxidant effects (21). It can be speculated that of the role of the *S. cordifolium* extract in preventing formation of CaOx calculi and disruption of them, as seen in the present study, is in part due to the anti-inflammatory and antioxidant effects of the different compounds of extract.

Conclusion

The present study was conducted to evaluate the antiurolithiatic activity of ethanolic extract of aerial parts of *S. cordifolium*. We could find that the extract of stem and leaves of *S. cordifolium* significantly decreased the number and size of CaOx deposits in different parts of the renal tubules. The antiurolithiatic activity of the plant may probably be due to synergism of diuretic activity, crystallization inhibition and improved renal function along with antioxidant activity. It also seems that the preventive properties of ethanolic extract are more effective than its treatment effect. Further studies on larger animal models and on human are required to draw final conclusions.
